## ABSTRACT

Tables and graphs are presented which give the angular distribution of scattered light from spherical particles having a refractive index 1.33 (e.g., water droplets in air). The 50 particle sizes include the size parameters 1(1)20, 22(2)50, 55(5)125, and the scattering angles  $0^\circ$ ( $0.2^\circ$ ) $180^\circ$  in the graphs and  $0^\circ$ ( $2^\circ$ ) $180^\circ$  in the tables. The computational procedure is given in detail, and the FORTRAN programs are listed.

## PROBLEM STATUS

This report completes one phase of the problem; work on other aspects of the problem is continuing.

## ANGULAR SCATTERING FUNCTIONS FOR SPHERICAL WATER DROPLETS

### INTRODUCTION

This report presents tables and graphs which describe the angular distribution of electromagnetic radiation scattered from spherical particles of refractive index 1.33 (e.g., water droplets in air). For incident light of wavelength 0.63  $\mu\text{m}$  (e.g., He-Ne laser) the range of particle size (radius) covered here is approximately 0.1 to 12.5  $\mu\text{m}$ . Droplets in this range (and larger) are commonly found in natural haze, fog, and clouds.

The data presented here are a portion of the results of extensive calculations made at NRL during an investigation (1) of the theoretical aspects of indirect, optical measurement of parameters describing the microstructure of fog and clouds. Some of the data presented here can be found in earlier works,\* but the combination of (a) size range, (b) resolution in scattering angle, and (c) inclusion of computer program listings are not, to the knowledge of the author, to be found elsewhere.

Since each investigation requiring data on light scattering usually involves an index of refraction, a particle size range, or an angle interval not covered by published data, it seemed practical to limit the scope of the tabulated data and graphs and to supplement this with the listings of rather simple computer programs, in FORTRAN, by which more detailed computations could be made for any particular application.

The purposes of this report are to provide the reader with a simplified but moderately detailed view of the nature of light scattering from spherical particles, and to present a convenient means by which further details can be obtained.

### THEORY

If a beam of light, or other electromagnetic radiation, of wavelength  $\lambda$  and flux density  $I_0$  (e.g.,  $\mu\text{W}/\text{cm}^2$ ) is incident on a spherical particle of radius  $r$  and refractive index  $m$ , then the total flux scattered over all directions is

$$E = I_0 C(m, \lambda, r) = I_0 Q(m, \lambda, r) \pi r^2 \mu\text{W},$$

where  $C$  is the scattering cross section of the particle, at wavelength  $\lambda$  and 0, the scattering efficiency factor, is the ratio of the scattering cross section to the geometric cross section ( $\pi r^2$ ) of the scattering particle. If the incident beam is polarized with the electric vector perpendicular to the plane of scattering (that plane which includes both the incident and emergent propagation vectors), the intensity  $i(\theta)$  in  $\mu\text{W}/\text{sr}$  scattered at an angle  $\theta$  as measured from the direction of the incident beam, is

$$I(\theta) = \frac{\lambda^2}{4\pi^2} I_0 i_i(\theta). \quad (1)$$

\*See Ref. 2, pp. 167-171, for a description of published data.

where  $i_1(\theta)$  is the Mie (3) intensity function for the perpendicular component of polarization. For incident light polarized with the electric vector parallel to the scattering plane, Eq. (1) would contain  $i_2(\theta)$ , the Mie intensity function for the parallel component of polarization. In the case of incident natural (unpolarized) light, the expression for  $I(\theta)$  becomes

$$I(\theta) = \frac{\lambda^2}{8\pi^2} [i_1(\theta) + i_2(\theta)] . \quad (2)$$

For a specified index of refraction, the scattering characteristics of a given spherical particle depend on the size of the particle relative to the incident wavelength. This is expressed as the size parameter  $x = 2\pi r/\lambda$ . In the following section, it will be seen that the parameters  $x$  and  $y (= mx)$  are the arguments of the functions from which  $i_1$ ,  $i_2$ , and  $\theta$  are eventually derived.

For a complete discussion of the Mie theory of light scattering, one should consult a text such as those given in Refs. 2, 4, and 5.

#### COMPUTATIONAL PROCEDURE

The basic set of coefficients from which  $i_1$ ,  $i_2$ , and  $\theta$  are obtained are

$$a_n = \frac{\Psi'_n(y) \Psi_n(x) - m \Psi'_n(y) \Psi'_n(x)}{\Psi'_n(y) \zeta_n(x) - m \Psi_n(y) \zeta'_n(x)} \quad (3a)$$

and

$$b_n = \frac{m \Psi'_n(y) \Psi_n(x) - \Psi'_n(y) \Psi'_n(x)}{m \Psi'_n(y) \zeta_n(x) - \Psi_n(y) \zeta'_n(x)} , \quad (3b)$$

where  $\Psi_n$  and  $\zeta_n$  are Riccati-Bessel functions (after the notation used by van de Hulst, Ref. 2). Making the substitution  $\Psi_n = S_n$  and  $\zeta_n = S_n + iC_n$  (where  $i = \sqrt{-1}$ ), the expressions for  $a_n$  and  $b_n$  become

$$a_n = \frac{S'_n(y) S_n(x) - m S_n(y) S'_n(x)}{S'_n(y)[S_n(x) + iC_n(x)] - m S_n(y)[S'_n(x) + iC'_n(x)]} \quad (4a)$$

and

$$b_n = \frac{m S'_n(y) S_n(x) - S_n(y) S'_n(x)}{m S'_n(y)[S_n(x) + iC_n(x)] - S_n(y)[S'_n(x) + iC'_n(x)]} . \quad (4b)$$

The functions  $C_n$  and  $S_n$  in terms of fractional-order Bessel functions of the first kind are

$$C_n(x) = (-1)^n \left( \frac{\pi x}{2} \right)^{1/2} J_{-n-(1/2)}(x) ,$$

and

$$S_n(x) = \left( \frac{\pi x}{2} \right)^{1/2} J_{n+(1/2)}(x) .$$

Dividing both numerator and denominator of Eqs. (4a) and (4b) by the product  $S_n(x) S_n(y)$ , and using the definitions

$$\text{SPSX}_n = S'_n(x)/S_n(x), \quad \text{SPSY}_n = S'_n(y)/S_n(y),$$

$$\text{CNSN}_n = C_n(x)/S_n(x), \quad \text{CPCX}_n = C'_n(x)/C_n(x),$$

with some rearrangement, we derive

$$a_n = \left\{ 1 + \left[ \frac{\text{CNSN}_n (\text{SPSY}_n - m \text{CPCX}_n)}{\text{SPSY}_n - m \text{SPSX}_n} \right] \right\}^{-1} \quad (5a)$$

and

$$b_n = \left\{ 1 + \left[ \frac{m \text{CNSN}_n (\text{SPSY}_n - \text{CPCX}_n)}{m \text{SPSY}_n - \text{SPSX}_n} \right] \right\}^{-1}. \quad (5b)$$

The ratios  $\{\text{CNSN}_n, \text{CPCX}_n, \text{SPSX}_n, \text{SPSY}_n\}$  were computed for  $n = 1, 2, 3, \dots, N$  using upward recurrence relations which follow from the well-known recurrence formula for Bessel functions (6),

$$J_{\nu-1}(x) + J_{\nu+1}(x) = \frac{2\nu}{x} J_\nu(x).$$

First, let

$$Q_n = J_{n-(1/2)}(y)/J_{n+(1/2)}(y),$$

$$R_n = J_{n-(1/2)}(x)/J_{n+(1/2)}(x),$$

and

$$U_n = J_{-n+(1/2)}(x)/J_{-n-(1/2)}(x).$$

Then, for  $n = 0$ ,

$$Q_0 = \cos y/\sin y,$$

$$R_0 = \cos x/\sin x,$$

$$U_0 = R_0^{-1},$$

and

$$\text{CNSN}_0 = R_0;$$

and for  $n = 1, 2, 3, \dots, N$ ,

$$Q_n = \left( \frac{2n+1}{y} - Q_{n-1} \right)^{-1}.$$

$$R_n = \left( \frac{2n+1}{y} - Q_{n-1} \right)^{-1},$$

$$U_n = \left( \frac{2n+1}{x} - U_{n-1} \right)^{-1},$$

and

$$\text{CNSN}_n = -\text{CNSN}_{n-1} R_n/U_n, \quad \text{SPSY}_n = Q_n - n/y,$$

$$\text{CPCX}_n = -U_n - n/x, \quad \text{SPSX}_n = R_n - n/x.$$

The termination value for the index ( $n = N$ ) depends on the size parameter, as illustrated in Fig. 1. The value of  $N$  was determined by the magnitudes of the real and imaginary parts of the current  $a_n$  and  $b_n$ . If the maxima of the quantities  $|\text{Re}(a_n)|$ ,  $|\text{Im}(a_n)|$ ,  $|\text{Re}(b_n)|$ , and  $|\text{Im}(b_n)|$  were less than a specified value, say  $10^{-9}$ , the computation of  $a_n$  and  $b_n$  was terminated. The degree of error resulting in truncating the infinite series defining  $i_1$ ,  $i_2$ , and  $Q$  according to the test given above was not significant (i.e., it did not affect the first five significant figures of  $i_1$  or  $i_2$ , or the first six decimal places of  $Q$ ).

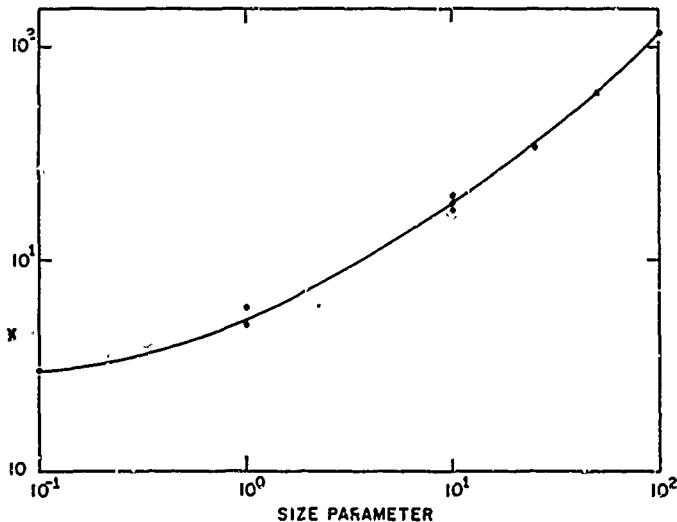

Fig. 1 - The number  $N$  of sets of Mie coefficients computed as a function of size parameter  $x$

The generation of Bessel functions of the first kind by upward recurrence is known to be error-unstable for orders much larger than the argument. A study was made comparing upward and downward recurrence methods of generating the necessary Bessel function ratios involved in the computation of  $a_n$  and  $b_n$ , and it showed that the simpler, upward recurrence technique produced no significant errors in  $i_1$ ,  $i_2$ , or  $Q$  for real indexes of refraction and for size parameters in the range  $0.2 \leq x \leq 750$ . This was because the errors introduced into  $a_n$  and  $b_n$  by upward recurrence became significant only when the magnitudes of  $a_n$  and  $b_n$  became very small, and thus contributed very little to the end result.

The scattering efficiency factor  $Q$  is obtained from

$$Q = \frac{4}{x^2} \sum_{n=1}^{\infty} \left( n + \frac{1}{2} \right) (|a_n|^2 + |b_n|^2) .$$

The exact value of  $Q$  would require an infinite number of terms, but the truncation of the series according to the criterion described above approximated the value of  $Q$  well enough that further computation failed to show any change in the first six decimal places.

For speedier computation of  $i_1$  and  $i_2$  a set of coefficients

$$\begin{Bmatrix} A_n \\ B_n \end{Bmatrix} = \frac{2n+1}{n(n+1)} \begin{Bmatrix} a_n \\ b_n \end{Bmatrix}$$

was used. Then

$$i_1(\theta) = \left| \sum_{n=1}^{\infty} [A_n \pi_n(\cos \theta) + B_n \tau_n(\cos \theta)] \right|^2 , \quad (6a)$$

$$i_2(\theta) = \left| \sum_{n=1}^{\infty} [B_n \pi_n(\cos \theta) + A_n \tau_n(\cos \theta)] \right|^2 , \quad (6b)$$

where  $\pi_n$  and  $\tau_n$  are related to the first and second derivatives ( $P'_n$  and  $P''_n$ ) of the Legendre polynomial

$$\pi_n(\cos \theta) = P'_n(\cos \theta) ,$$

$$\tau_n(\cos \theta) = (\cos \theta) P'_n(\cos \theta) - (1 - \cos^2 \theta) P''_n(\cos \theta) .$$

Using the differential equations which relate the Legendre polynomial  $P_n$  to  $P'_n$  and  $P''_n$  (e.g., see Ref. 2, p. 115) we can derive the following recurrence relations for  $P'_n$  and  $P''_n$  (and hence  $\pi_n$  and  $\tau_n$ ):

$$P'_{n+1}(\cos \theta) = \frac{1}{n} [(2n+1)(\cos \theta) P'_n(\cos \theta) - (n+1) P'_{n-1}(\cos \theta)] , \quad (7a)$$

$$P''_{n+1}(\cos \theta) = (2n+1) P'_n(\cos \theta) + P''_{n-1}(\cos \theta) . \quad (7b)$$

#### COMPUTER PROGRAMS

The complex coefficients  $A_n$  and  $B_n$  are computed by the subroutine MLECORL (listed on page 62). The specified parameters are the size parameter ( $x$ ) and the index of refraction (EMU). The following quantities are returned:

A: real part of $A_n$	for $n = 1, 2, 3, \dots, NMAX$
AI: imaginary part of $A_n$	
B: real part of $B_n$	
BI: imaginary part of $B_n$	
NMAX: maximum value of $n$	

Q: scattering efficiency factor

Two subroutines, SCREC and ABRIM, are called by MIECORL. SCREC returns the Bessel function ratios SPSX, SPSY, CPCX, and CNSN for each value of  $n$  ( $= IN$ ). The specified parameters are the size parameter  $X$  and the product  $Y$  of the index of refraction times the size parameter. The quantities returned from SCREC and the index of refraction are immediately sent to ABRIM, which returns:

ARL: real part of  $a_n$   
 AIM: imaginary part of  $a_n$   
 BRL: real part of  $b_n$   
 EIM: imaginary part of  $b_n$

In the subroutine MIECORL, the quantity ACCY (here ACCY =  $10^{-10}$ ) is the value with which the magnitudes of the real and imaginary parts of  $A_n$  and  $B_n$  are compared to determine when the computation of  $A_n$  and  $B_n$  is to be terminated. If the test has not been satisfied (i.e., if the magnitudes of the tested quantities remain larger than ACCY) after NSTOP sets of coefficients have been computed, NSTOP (computed in MIECORL) is taken as the maximum value of  $n$ , a message to this effect is printed out, and the program continues on its normal course.

The angular scattering functions  $i_1$  and  $i_2$  are computed in subroutine MIESD, listed on p. 11. The specified parameters are

A: real part of $A_n$	for $n = 1, 2, 3, \dots, NCOFS$
AI: imaginary part of $A_n$	
B: real part of $B_n$	
BI: imaginary part of $B_n$	

NCOFS: maximum value of  $n$  (NCOFS = NMAX)  
 COSTH: the array of values of  $\cos \theta$  ( $\theta$  is the scattering angle) for which  $i_1(\theta)$  and  $i_2(\theta)$  are to be computed  
 NANG: the number of values of  $\cos \theta$  in the array COSTH.

The following quantities are returned by MIESD for NANG-specified scattering angles:

EA:  $i_1$

EB:  $i_2$

EC:  $\sqrt{i_1 i_2 \cos \delta}$

ES:  $\sqrt{i_1 i_2 \sin \delta}$ .

The angle  $\delta$  is the phase difference between  $i_1$  and  $i_2$ . The quantities EC and ES are of interest in the scattering of arbitrarily polarized light (see Ref. 2, pp. 34-35).

The programs described above and listed in Appendix A were run on the CDC-3800 digital computer at NRL. Table 1 gives the computing times required for several size parameters, when the specified number of angles was 37. The quantity  $t_1$  is the time (in seconds) required to compute NMAX sets of coefficients  $A_n$  and  $B_n$ , and  $t_2$  is the computation time required for the scattering functions.

Table 1  
Computing Time for Mie Coefficients  
and Scattering Functions

x	NMAX	$t_1$ (sec)	$t_2$ (sec)
0.02	3	0.004	0.059
1.0	5	0.006	0.096
10.0	17	0.024	0.302
25.0	34	0.041	0.607
100.0	114	0.126	2.129

#### TABLES AND GRAPHS

The angular scattering (intensity) functions  $I_1(\theta)$  and  $I_2(\theta)$  presented in the tables of Appendix B and graphs of Appendix C are related to the Mie intensity functions ( $i_1$  and  $i_2$ ) by a constant factor (for all sizes), i.e.,

$$\begin{Bmatrix} I_1(\theta) \\ I_2(\theta) \end{Bmatrix} = f \begin{Bmatrix} i_1(\theta) \\ i_2(\theta) \end{Bmatrix}.$$

The factor  $f = 3.55573 \times 10^{-8}$  was applied for convenience in the study (1) for which the computations were made (the computer programs listed here, however, do not apply this factor, so that the intensities computed by MIESD are the Mie intensity functions).

The tables and graphs are given for 50 size parameters: 1(1)20, 22(2)50, and 55(5)125 (where 22(2)50, for example, is abbreviated notation for 22, 24, 26, ..., 50).

The graphs were plotted from data computed for scattering angles  $0^\circ$  to  $180^\circ$  and the tables include the angles  $0^\circ$  to  $180^\circ$ . For large size parameters the  $2^\circ$  angular interval does not allow definition of the angular variation of intensity. To tabulate the

intensities at smaller angular intervals would result in very lengthy tables, and thus the graphs were included to furnish the detail lacking in the tables.

The graphs show three curves, with the ordinate on a (base 10) logarithmic scale:

$$I_1(\theta) \times 10^{-N} \text{ (lowest curve).}$$

$$I_2(\theta) \times 10^{-1} \text{ (middle curve).}$$

$$I_1(\theta) + I_2(\theta) \text{ (uppermost curve).}$$

Each set of three graphs is for a given size parameter  $x$ , specified at the top of the graph. The factors were applied to separate the curves, and the factor  $10^{-N}$  (not the same for each graph) may easily be determined by counting the number of decades between the two lower curves at either  $0^\circ$  or  $180^\circ$ . For example, in the first graph (for  $x = 1$ ) the lowest curve is three decades below the middle curve at  $180^\circ$ , and including the one decade by which the middle curve was shifted, we see that  $N = 4$ , or that the lowest curve is of  $I_1(\theta) \times 10^{-4}$ .

The scattering efficiency factor  $Q$  is given at the top center of each table, just below the size parameter.

The accuracy of the data was checked by running the programs for values of refractive index, size parameter, and scattering angles for which published data existed. On the basis of those comparisons, it is believed that the angular functions are accurate to at least four significant figures and the scattering efficiency factors accurate to six decimal places.

#### ACKNOWLEDGMENT

The computational procedure and basic programs (ABRIM, PECUR, SCREC) presented in this report were developed by Dr. S. Twomey (a former member of the NRL scientific staff), to whom the author is deeply indebted.

Appendix C  
GRAPHS OF ANGULAR SCATTERING FUNCTIONS

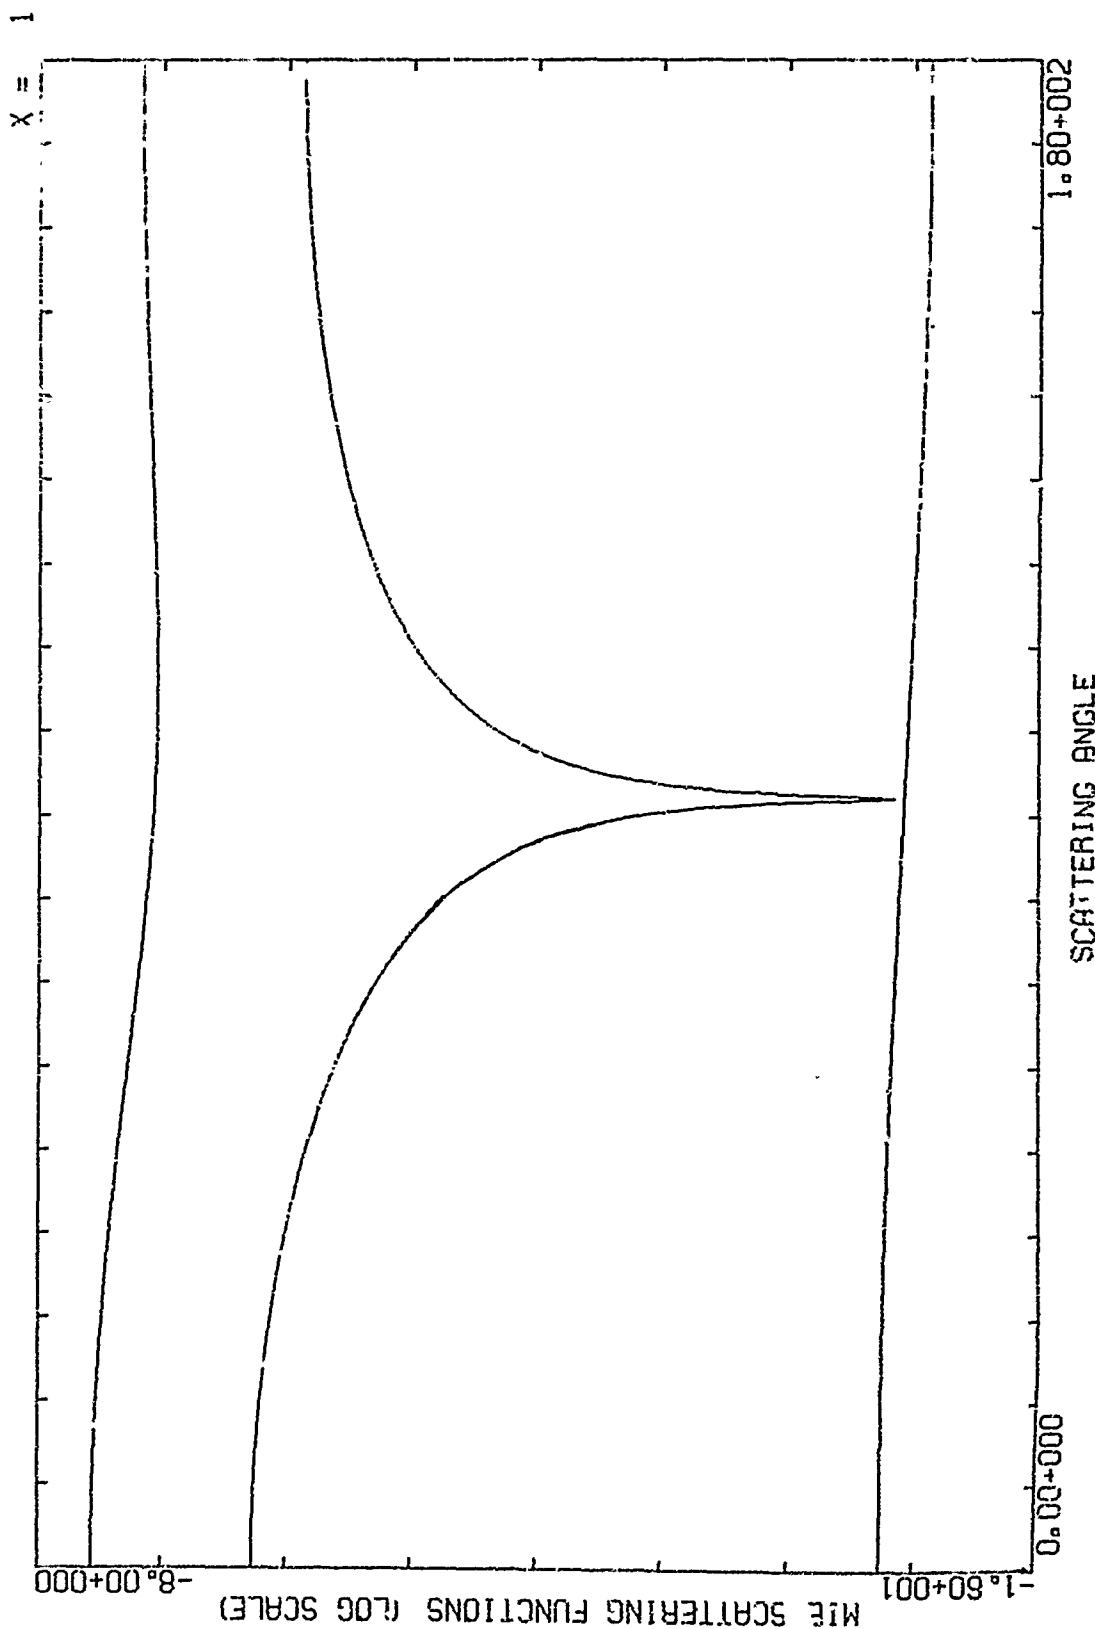

The following pages comprise graphs of the scattering functions

$$I_1(\theta) \times 10^{-N}, \text{ (lowest curve)}$$

$$I_2(\theta) \times 10^{-1}, \text{ (middle curve)}$$

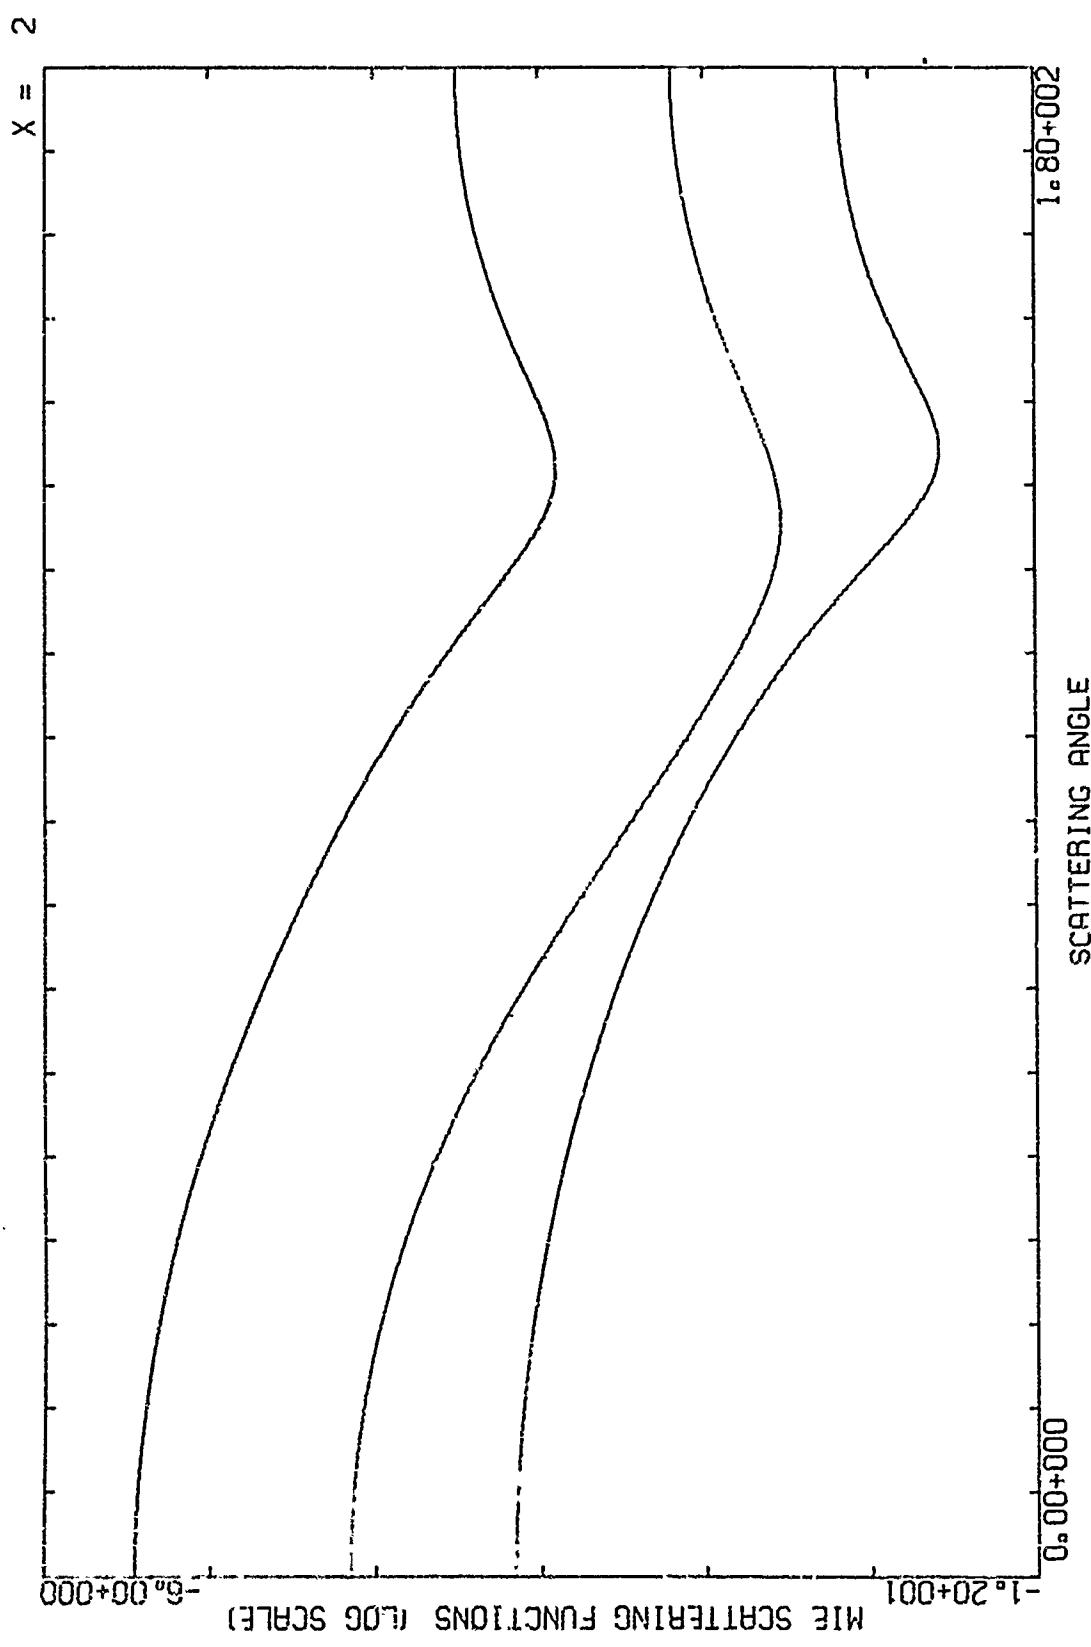

$$I_1(\theta) + I_2(\theta), \text{ (top curve)}$$

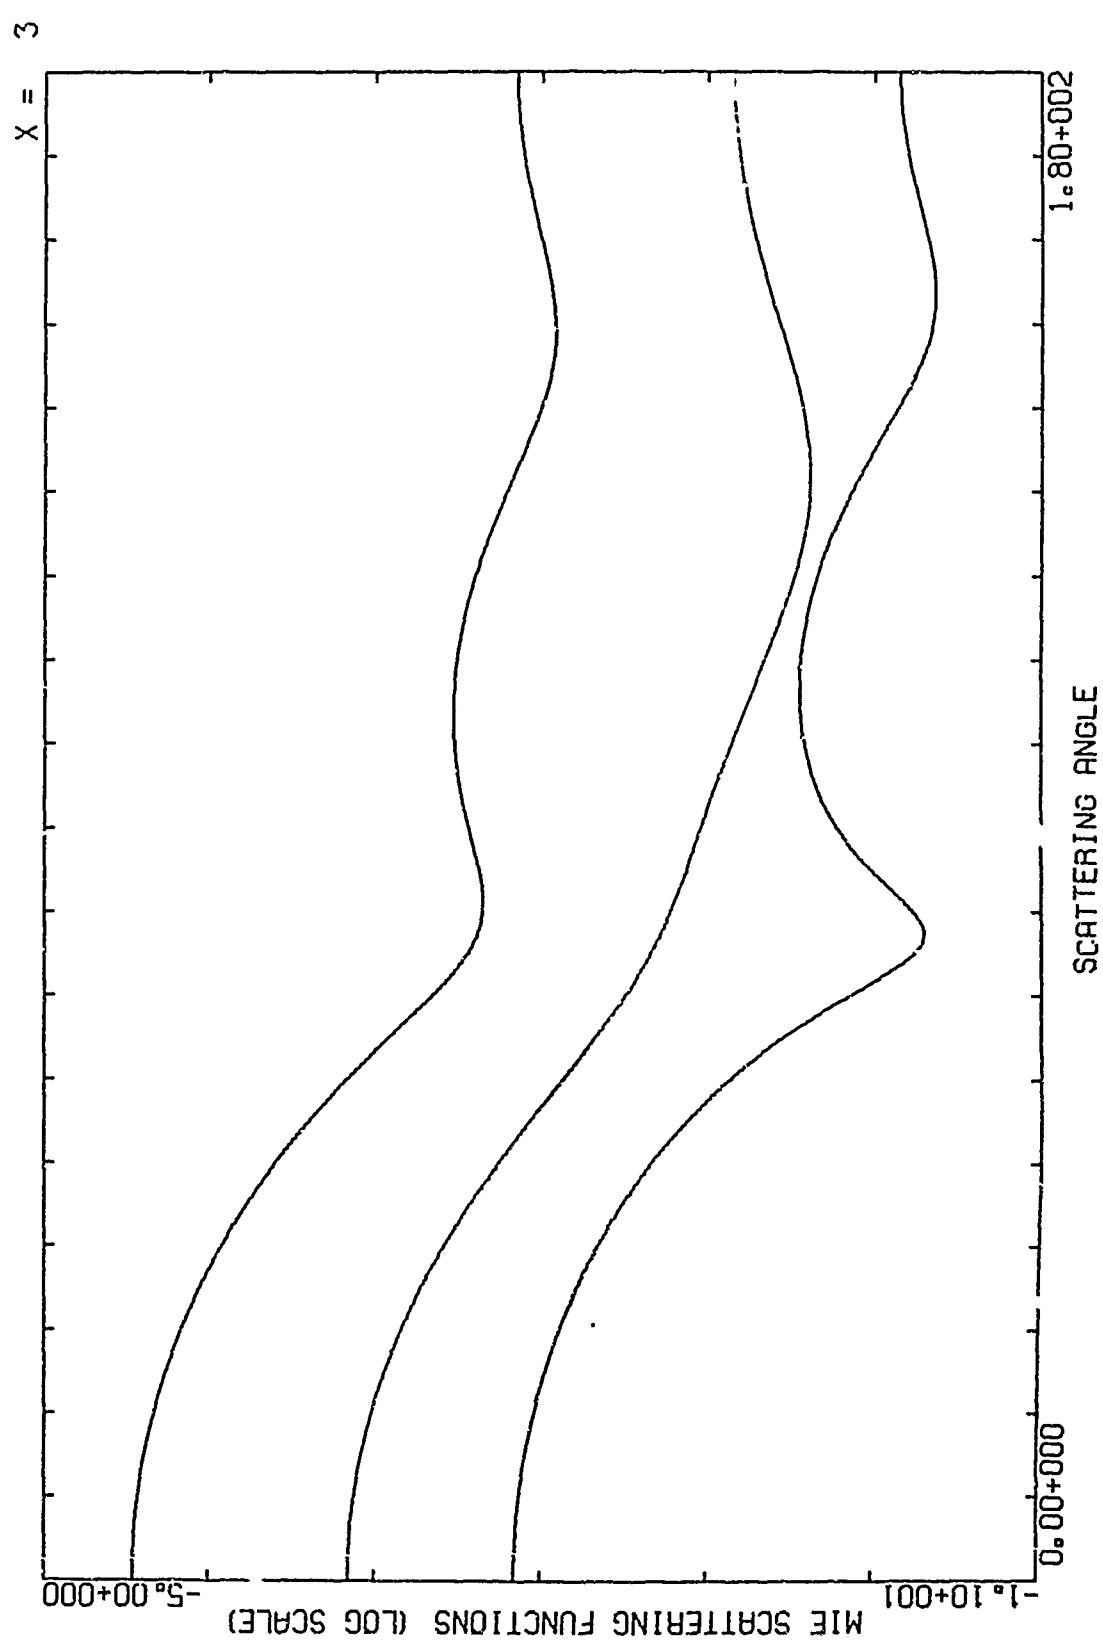

In the text, p. 8 gives the method of determining the  $10^{-N}$  factor.

<b>13. ABSTRACT</b> Tables and graphs are presented which give the angular distribution of scattered light from spherical particles having a refractive index 1.33 (e.g., water droplets in air). The 50 particle sizes include the size parameters 1(1)20, 22(2)50, 55(5)125, and the scattering angles 0°(0.2°)180° in the graphs and 0°(2°)180° in the tables. The computational procedure is given in detail, and the FORTRAN programs are listed.
